1. INTRODUCTION

The QCD phase diagram has been focus of intense research in the last decades. The conjecture for the existence of a critical endpoint (CEP) of first order phase transitions in the QCD phase diagram is the basis for recent as well as future beam energy scan (BES) programs in relativistic heavy-ion collision experiments at RHIC, SPS, NICA and FAIR which try to identify the parameters of its position ($T_{\text{CEP}}, \mu_{\text{CEP}}$). The theoretical situation is very unsatisfactory since the predictions for this position form merely a skymap in the $T–\mu$ plane [1]. Quantitative calculations of the phase diagram based in QCD are extremely complicated in the low energy regime due to its strong coupling. In this region non-erterturbative methods are powerful tools to describe the chiral and deconfinement transitions. Lattice QCD calculations have the sign problem at finite chemical potential. Therefore, the effective models play a crucial role to describe the phase diagram, specially at finite densities.

The now well-established results from lattice QCD at zero and small chemical potential $\mu$, predict coincident chiral and deconfinement crossover transitions at a pseudocritical temperature of $T_c(0) = 154 \pm 9$ MeV for $2+1$ flavors [2] and a value of $T_c(0) \sim 170$ MeV for two flavors [3].

A possible strategy for extending these benchmark results to the so far inaccessible regions of the QCD phase diagram is to use effective theories for the low-energy sector of QCD, which reproduce lattice results at vanishing and small $\mu$, and systematically extend the predictions to high chemical potential without changing the model inputs fixed with lattice results for the QCD vacuum. That leaves us with a variety of possibilities for the phase structure at nonzero $\mu$, depending on the effective model.

Among them we want to mention the following ones:

- no CEP at all [4], since the transition is crossover in the whole phase diagram,
- no CEP, but a Lifshitz point [5],
- one CEP, but with largely differing predictions of its position [1],
- second CEP [6–9],
- several CEPs [10, 11],
- CEP and triple point, possibly coincident, due to another phase (i.e. colour superconducting [12] or quarkyonic matter [13]) at low temperatures and high densities.

This spectrum of possibilities is rather broad in view of the upcoming experimental programmes. It is crucial to analyze the predictions arising from effective models for their compatibility with lattice results.

One of the effective models that accounts for dynamical breaking of chiral symmetry and its restoration at finite $T$ and $\mu$ is the Nambu–Jona-Lasinio (NJL) model [14–17]. The absence of confinement in...
this model is partially cured by coupling its chiral quark sector to the Polyakov-loop variable and adjusting a suitable potential with a temperature dependence that is adjusted to describe the pressure in accordance with lattice QCD simulations in the pure gauge field system [18–20]. These PNJL models provide a straightforward approach to the behaviour of chiral and Polyakov-loop order parameters in the T–μ plane (the phase diagram, see also [21, 22]) and predict a position for the CEP.

It has been shown that the non-local version of the PNJL model, reproduces hadron properties at zero density and temperature and presents some advantages over the local model [23–25]. As another feature, one can add to the model a vector repulsive interaction which increases the stiffness of quark matter and is therefore indispensable to discuss under the observational constraint of 2 M⊙ neutron stars [26, 27] the possibility of quark matter phases in their interiors [28–32]. Such astrophysical applications have recently also been considered within the nonlocal PNJL model [33–36].

Our aim in the present paper is to make a systematic study of the location of the CEP based on chiral quark models constrained from lattice results, including all interactions mentioned above. We tune the parameters of our model to reproduce lattice results at zero density and then we extrapolate our predictions to regions of finite density or chemical potential.

This article is organized as follows. In Section 2 we present the description of the model and the parameterizations we used. In Section 3 we show our results for the different form factors and parameters. Then, in Section 4 we present our conclusions.

2. GENERAL FORMALISM

Let us start describing the general formalism of the model we used. In the present work we considered a non local SU(2)_c chiral model, including vector interactions as well as quark couplings to the gauge color background fields.

2.1. Nonlocal Chiral Quark Model

The corresponding Lagrangian of the model used in this work is given by

\[ \mathcal{L} = \bar{q}(i\not{\partial} - m_0)q + \mathcal{L}_{\text{int}} + \mathcal{U}(\Phi), \]  

where \( q \) is the \( N_f = 2 \) fermion doublet \( q = (u, d)^T \), and \( m_0 \) is the current quark mass (we consider isospin symmetry, that is \( m_u = m_d = m_0 \)). The covariant derivative is defined as \( D_\mu \equiv \partial_\mu - iA_\mu \), where \( A_\mu \) are color gauge fields.

The nonlocal interaction channels are given by

\[ \mathcal{L}_{\text{int}} = -\frac{G_f}{2} [j_a(x)j_a(x) - j_f(x)j_f(x)] - \frac{G_f}{2} j_f(x)j_f(x), \]  

where the nonlocal currents are

\[ j_a(x) = \int d^4z \ g(z)\bar{q}(x + \frac{z}{2})\Gamma_a q(x - \frac{z}{2}), \]

\[ j_f(x) = \int d^4z \ f(z)\bar{q}(x + \frac{z}{2})\gamma^\mu q(x - \frac{z}{2}), \]

\[ j_f(x) = \int d^4z \ g(z)\bar{q}(x + \frac{z}{2})\gamma^\mu q(x - \frac{z}{2}) \]

with \( \Gamma_a = (\Gamma_3, \Gamma_\rho) = (1, i\gamma_5\tilde{\tau}) \) for scalar and pseudoscalar currents respectively, and \( u(x)'\partial^\mu v(x) = u(x)'\partial_\mu v(x) - \partial_\mu u(x) v(x) \). The functions \( g(z) \) and \( f(z) \) are nonlocal covariant form factors. The scalar-isoscalar component of the \( j_a(x) \) current is the responsible for the momentum dependence of the quark mass in the quark propagator. Then, the current \( j_f(x) \) will generate a momentum dependent wave function renormalization (WFR) of this propagator. The mass parameter \( \kappa \) controls the relative strength between both interaction terms in (3). Finally, \( j_f(x) \) represents the vector channel interaction current, whose coupling constant \( G_f \) is usually taken as a free parameter. Moreover, we also have considered in this vector interaction the same nonlocal covariant form factor \( g(z) \) used for the scalar and pseudoscalar currents. Then it is not necessary to include new free parameter in this term.

After the Fourier transform into momentum space, we have performed a standard bosonization of the theory introducing the bosonic fields \( \sigma_1, \sigma_2(p) \) and \( \omega(p) \) and integrate out the quark fields. Furthermore, as we work within the mean field approximation (MFA), we replace the bosonic fields by their vacuum expectation values \( \langle \sigma_1, \sigma_2 \rangle \) and \( \omega \), respectively, and the corresponding fluctuations are neglected. The main motivation of the present work is to study the phase diagram of the strongly interacting quark matter. As we want to analyze the chiral phase transition for different choices of the parameters of the model, we have to include the dependence on the temperature \( T \) and quark chemical potential \( \mu \) in our effective action. In the present work this is carried out by using the Matsubara imaginary time formalism. As mentioned above, the quarks are coupled to the gluons in (1) through the covariant derivative.

\(^2\)The \( \mu_B \) can be easily obtained from the relation \( \mu_B = 3 \mu \).
The coupling of fermions with the gluon fields is taken into account in (1) through the covariant derivative. Considering the quarks in a color field background \( A_0 = g_0 G^a_0 \lambda_0 / 2 \), where \( G^a_0 \) are the \( SU(3) \) color gauge fields. At mean field level the traced Polyakov loop is given by \( \Phi = 1/3 \text{Tr} \exp(i\beta \phi) \), with \( \phi = iA_0 \).

Then, in the Polyakov gauge, the matrix \( \phi \) is given by \( \phi = \phi_3 \lambda_3 + \phi_8 \lambda_8 \). Considering that the mean field expectation values of \( \Phi \) must be real, we set \( \phi_8 = 0 \) [19, 25]. Then, the mean field traced Polyakov loop is then given by \( \Phi = \Phi^* = [1 + 2 \cos(\phi_3 T)] / 3 \). Finally, the lagrangian (1) also includes an effective potential \( \mathcal{U} \) that accounts for gauge field self-interactions and will be briefly described below.

Within this framework the mean field thermodynamical potential \( \Omega^{\text{MFA}} \) results

\[
\Omega^{\text{MFA}} = -4T \sum_c \sum_n \left[ \frac{d^3 \vec{p}}{(2\pi)^3} \ln \left( \frac{\langle \rho_{n,b}^c \rangle^2 + M^2(\rho_{n,b}^c)}{Z^c(\rho_{n,b}^c)} \right) \right. \\
+ \frac{\sigma_1^2 + \sigma_2^2 \omega^2}{2G_S} - \omega^2 \frac{\lambda_3^2}{2G_V} + \mathcal{U}(\Phi, T)
\]

where \( M(p) \) and \( Z(p) \) are given by

\[
M(p) = Z(p) \left[ m + \sigma_1 g(p) \right], \\
Z(p) = \left[ 1 - \sigma_2 f(p) \right]^{-1}.
\]

Finally, as in [37] we have considered

\[
\langle \rho_{n,b}^c \rangle = [2(n+1) \pi T - i\mu + \phi_c] \left[ \frac{\omega}{2} + \tilde{p}^2 \right],
\]

where \( \phi_c \) are given by the relation \( \phi = \text{diag}(\phi_r, \phi_g, \phi_b) \). Namely, \( \phi_c = c\phi_3 \) with \( c = 1, -1, 0 \) for \( r, g, b \), respectively.

For finite values of the current quark mass, \( \Omega^{\text{MFA}} \) turns out to be divergent. The regularization procedure used here considers [37, 38]

\[
\Omega_{\text{(reg)}}^{\text{MFA}} = \Omega^{\text{MFA}} - \Omega^{\text{free}} + \Omega_{\text{(reg)}}^{\text{free}},
\]

where \( \Omega^{\text{free}} \) is obtained from (4) for \( \sigma_1 = \sigma_2 = 0 \), and \( \Omega_{\text{(reg)}}^{\text{free}} \) is the regularized expression for the thermodynamical potential of a free fermion gas,

\[
\Omega_{\text{(reg)}}^{\text{free}} = -4T \int \frac{d^3 \vec{p}}{(2\pi)^3} \left[ \ln \left( 1 + e^{-\left( \beta \vec{p}^2 + m^2 + i\mu \right)/T} \right) \right. \\
+ \ln \left( 1 + e^{-\left( \beta \vec{p}^2 + m^2 + i\mu \right)/T} \right) \right] .
\]

The next step is obtaining the mean field values of \( \sigma_1, \sigma_2, \omega \) and \( \Phi \) as a function of the chemical potential and the temperature, by solving the following set of coupled equations

\[
\frac{d\Omega_{\text{(reg)}}^{\text{MFA}}}{d\sigma_1} = 0, \quad \frac{d\Omega_{\text{(reg)}}^{\text{MFA}}}{d\sigma_2} = 0, \quad \frac{d\Omega_{\text{(reg)}}^{\text{MFA}}}{d\omega} = 0,
\]

\[
\frac{d\Omega_{\text{(reg)}}^{\text{MFA}}}{d\Phi} = 0.
\]

Then we can evaluate \( \Omega_{\text{(reg)}}^{\text{MFA}} (\sigma_1, \sigma_2, \omega, \Phi, \mu, T) \) and compute all the relevant thermodynamic quantities needed in our calculation, like the chiral quark condensate

\[
\langle \bar{\psi} \psi \rangle = \frac{\partial \Omega_{\text{(reg)}}^{\text{MFA}}}{\partial \mu}, \quad \rho_q = \frac{\partial \Omega_{\text{(reg)}}^{\text{MFA}}}{\partial \mu}.
\]

and the chiral susceptibility \( \chi \) which can be used to determine the characteristic of the chiral phase transition

\[
\chi_{ch} = -\frac{\partial^2 \Omega_{\text{(reg)}}^{\text{MFA}}}{\partial m^2} = -\frac{\partial \langle \bar{\psi} \psi \rangle}{\partial m}.
\]

To proceed, we still have to define some quantities like the form factors, the vector interactions, the effective potential \( \mathcal{U} \) and as well the parameters of the model. Let us introduce them gradually.

### 2.2. Form Factors

and Wave Function Renormalization

Following [37, 39], we have considered two different types of functional dependency for the form factors \( g(q) \) and \( f(q) \):

exponential forms

(Set A) \[ g(p) = \exp(-p^2/\Lambda_0^2) \]

(Set B) \[ f(p) = \exp(-p^2/\Lambda_1^2) \]

and Lorentzians with WFR

(Set C) \[
\begin{align*}
\left\{ \begin{array}{l}
g(p) = \frac{1 + \alpha_z}{1 + \alpha_z f_z(p)} f_z(p) \\
n(p) = \frac{1 + \alpha_z}{1 + \alpha_z f_z(p)} f_z(p)
\end{array} \right.
\]

where

\[
f_z(p) = \left[ 1 + \left( p^2/\Lambda_0^2 \right)^{3/2} \right]^{-1},
\]

\[
f_z(p) = \left[ 1 + \left( p^2/\Lambda_1^2 \right)^{5/2} \right]^{-1}.
\]
and \( \alpha_m = 309 \text{ MeV}, \alpha_c = -0.3 \). All the parameter sets are summarized in the table.

In addition, we want to include in our analysis the results arising from a local PNJL model, what allow us to compare with the results obtained for example in [4]. For that purpose, we started from the Lagrangian in [21] with two flavors instead of three and we use the same model parameters as in [18, 19, 40]:

\[
m = 5.5 \text{ MeV}, \quad G = 10.1 \text{ GeV}^{-2}, \quad \Lambda = 650.0 \text{ MeV. (16)}
\]

The model inputs can be constrained with results from lattice QCD studies. In particular, the above described form factors of the nonlocal interaction have been chosen [39] such as to reproduce the dynamical mass function \( M(p) \) and the WFR \( Z(p) \) of the quark propagator in the vacuum [41]. In Fig. 1 we show the shapes of normalized dynamical masses and WFR for the models under discussion here, i.e., the nonlocal models with set A (rank-one), set B and set C (rank-two) parameterizations as well as the local limit.

This figure generalizes the corresponding Fig. 1 in [39], by including the local limit for \( M(p) \) and showing the line \( Z(p) = 1 \) for both, set A and the local case. For comparison, a more recent lattice data from [42] is also included. It is easy to recognize the better agreement between the lattice results and the more complete model, namely nonlocal PNJL with WFR, in its two form factor parameterizations given by set B and set C.

### 2.3. The Vector Coupling

The vector coupling constant \( G_V \) is considered a free parameter which in the mean field approximation (MFA) may be adjusted such as to reproduce the behavior of the critical temperature, \( T_c(\mu) \), which has recently been obtained by Taylor expansion technique in lattice QCD [43]

\[
T_c(\mu)/T_c(0) = 1 - \kappa(\mu/T)^2 + O[(\mu/T)^4],
\]

with \( \kappa = 0.059(2)(4) \) being the curvature. Note that this result is not yet based on continuum extrapolated lattice results, so that discretization errors has to be expected. However, we are interested to present here a scheme for constraining effective QCD models. The quality of predictions can subsequently be improved by using better lattice QCD data and constant discretization schemes. In what follows, the vector coupling strength will be evaluated by considering different ratios of \( \eta_V = G_V/G_S \) and we use this parameter to tune our model to obtain better agreement with lattice predictions.

We include the vector coupling as a shifting in the chemical potential according to

\[
\tilde{\mu} = \mu - \omega g(p)Z(p).
\]

Note that we include the WFR \( Z(p) \) in the shifted chemical potential in order to keep the thermodynamical potential at mean field level. We found that the results are quite different if the \( Z(p) \) had not been included into the shift. As an example of that, we show in Fig. 2 the phase diagram for set B with and without WFR in \( \tilde{\mu} \), for a particular value of \( \eta_V \) (similar results were obtained within set C) and a finite value of vector coupling constant.

Finally we have to include the shifting (18) in (6) defining a new \( \tilde{\rho}_{n, \beta} \).

In the case of the local model, we consider that the chemical potential is shifted by

\[
\tilde{\mu} = \mu - \omega.
\]

### Results

Fig. 1. (Color online) Normalized dynamical masses (a) and wave function renormalization (b) for the different nonlocal form factors under study from [37, 39] fitted to lattice data from [41]. For comparison the local model [40] and more recent lattice data from [42] are also included.
2.4. Polyakov-Loop Potential

In the present work we have chosen a \( \mu \)-dependent logarithmic effective potential described in [44]

\[
\begin{align*}
\Psi(\Phi, T, \mu) &= (a_0 T^4 + a_1 \mu^4 + a_2 T^2 \mu^2)\Phi^3 + a_3 T^4 \ln(1 - 6\Phi^2 + 8\Phi^3 - 3\Phi^4),
\end{align*}
\]

where \( a_0 = -1.85, a_1 = -1.44 \times 10^{-3}, a_2 = -0.08, a_3 = -0.40 \).

The reason for our particular election is that we want to consider the influence of chemical potential on the PL effective potential, and evaluate how this \( \mu \)-dependence can modify the phase diagram, tuning the vector coupling. In the Fig. 3 we compare the phase diagrams we obtained considering the \( \mu \)-dependent logarithmic effective potential and a non-\( \mu \)-dependent effective potential described in [19]. The results for Set A and C have a similar qualitative behavior. As expected, at \( T = 0 \) and \( \mu = 0 \) both potentials produce the same critical temperatures, but there is a significant difference in the location of the CEPs. Nevertheless, it is shown in the same figure, that this difference turns to be smaller when increasing the vector coupling strength.

Another point we have to discuss here is the election of the critical temperature \( T_0 \) for deconfinement transition. In the present work we set \( T_0 \) for deconfinement by using the value corresponding to two flavors, i.e. \( T_0 = 208 \text{ MeV} \), as it has been suggested in [45], and used in subsequent approaches, including the nonlocal PNJL [46], Polyakov loop-DSE models [47] and entanglement PNJL (EPNJL) model [48, 49]. This election produces lower \( T_c \) values for the chiral transition (see Fig. 4 as an example), obtaining at zero chemical potential closer values to the lattice QCD more accepted result [3] for the critical temperature \( T_c(0) = 170 \text{ MeV} \). It is remarkable that within the local model the obtained critical temperatures are noticeably higher than in the case of nonlocal models, as it is shown in Fig. 4.

In this context it is important to keep in mind the effect that the account for a hadronic phase can have...
on the topology of the QCD phase diagram [50, 51], as well as higher order quark interactions [52].

3. RESULTS

The first effect we want to study is how the vector interactions affect the transitions and the location of the CEP. We built the corresponding phase diagrams for different values of $\eta_V$. In all the cases we observed a variation in the curvatures even at low chemical potential. As expected, the influence of the vector coupling increases with the chemical potential, then the position of the CEP and the values of $\mu_c(T = 0)$ reflect notably this influence. We want to remark that, for increasing $\eta_V$, the CEPs tend to be located towards lower $T$ and higher $\mu$. Similarly to what has been shown in [53], we observe that for any the nonlocal models under study, the CEPs (and the corresponding first order transitions) are still present for all the values of vector coupling constant analyzed in this work. In Fig. 5 it can be seen that effect for Set B (qualitatively similar behavior was observed for set A and set C). Nevertheless, for the local model, we observe that increasing $\eta_V$ a crossover line without a CEP is obtained, as it is shown in Fig. 6.

Once we have the phase diagrams, the next step is to determine the curvatures. To do so, we plotted the pseudocritical temperatures of the crossover transitions as function of $(\mu/T)^2$ for different $\eta_V$ ratios. Then, the curvatures can be obtained from the slope of the straight lines in the region of low $(\mu/T)$ values. An example of this is shown in Fig. 7 for set C (the corresponding plots for the other sets are qualitatively very similar). The fit of the lattice QCD results (17) is also shown. The grey zone corresponds to the error in the coefficient $\kappa$ obtained in [43].

In Fig. 8 we compare the lattice result with the values for the coefficient $k$ obtained within the nonlocal PNJL models and the local one. There, the horizontal line corresponds to the lattice QCD prediction of $\kappa = 0.059(2)(4)$ [43] and the grey zone represents its error. Note that for the more complete model (set B and set C) the curvatures are closer to each other than in the case of set A and local ones. It is important to remark that while the analysis of $\kappa$ has been performed for $N_f = 2 + 1$ simulations, the chemical potential $\mu$ concerns only the two light fla-

![Fig. 5](image-url) (Color online) Influence of the strength of the vector coupling (here $\mu_V = G_V/G_S$) on the phase diagram for set B. Dashed lines represent Crossover transitions, the symbols indicate the critical end points locations, and solid lines are first order phase transitions.

![Fig. 6](image-url) (Color online) Influence of the strength of the vector coupling on the phase diagram for the local model. Dashed lines represent Crossover transitions, the symbols (dot or square) indicate the critical end points location, and solid lines are first order phase transitions. It can be seen that CEPs tend to disappear for $G_V > 0.1 G_S$, leaving only a crossover phase transition.

![Fig. 7](image-url) (Color online) Chiral crossover transitions at low values of $\mu/T$ for different values of strengths of the vector coupling $\eta_V = G_V/G_S$ for Set C. The dashed line corresponds to the lattice QCD prediction of $\kappa = 0.059(2)(4)$ [43].
Therefore, our extraction of $\kappa$ from the nonlocal PNJL models for the 2-flavor case may be in order.

In Fig. 9 it is compared the phase diagrams for the nonlocal models discussed in this work, considering the corresponding $\eta_V$ values that best fit the lattice QCD prediction of $\kappa = 0.059(2)(4)$ from \cite{43}. The grey zones correspond to the range of $\eta_V$ values obtained by considering the error in the lattice determination of $\kappa$ \cite{43}. Similarly, the error bars in the CEP’s indicate the distances to the CEP positions for the corresponding $\eta_V$ values that fit the error limits.

Note that using the Polyakov loop potential (20) from \cite{44}, a crossover region and a CEP can be obtained for set A, even for $T_0 = 208$ MeV, contrarily to what has been reported in \cite{46, 47}, where the Polyakov loop potential from \cite{19} has been used.\footnote{Note that in the low-\(\mu\) region the differences in the chiral transition obtained with each effective potential are mainly due to the definition of the corresponding logarithmic term in the Polyakov loop potential.}

The results summarized in Figure 10 indicate that the absolute value of the critical temperature $T_c(0)$ of nonlocal covariant PNJL models is rather insensitive to the choice of the form factors parametrizing, the momentum dependence of dynamical (running) mass function and WFR of the quark propagator as measured on the lattice at zero temperature \cite{41}, whereas the position of the CEP and critical chemical potential at $T=0$ strongly depends on it. On the other hand, the
value of \( T_c(0) \) in the local model is significantly different (larger) than in the nonlocal ones. In addition, note that in the local model to fit the lattice QCD value requires a larger vector coupling, for which the corresponding phase diagram lacks of CEP and all the chiral phase transition is a crossover. This is another remarkable difference with respect to the obtained with non local models [4].

The nonlocal model for set B and set C cases, contains WFR and dynamical (running) quark mass effects and thus is closer to full QCD. Therefore, we suggest that statements about the existence and location of the CEP within set A and the local model should be less trustworthy than those of set B and set C. As a consequence, a possible region for the CEP location suggested by our study would be between the results for set B and set C, i.e. around \((T_{\text{CEP}}, \mu_{\text{CEP}}) = (129.8 \text{ MeV}, 276.6 \text{ MeV})\) and \((69.9 \text{ MeV}, 319.1 \text{ MeV})\), respectively.

This suggests that the search for CEP signatures in the BES programs is justified and should be continued. The energy range of the NICA and FAIR facilities shall be particularly promising.

4. SUMMARY AND CONCLUSIONS

In this work, based on nonlocal PNJL models with and without WFR, it is studied the influence of vector coupling strength in the QCD phase diagram. As shown in Fig. 2, it is observed a remarkable difference when the chemical potential shifting includes the WFR function, keeping the thermodynamical potential at mean field level. In a further exploratory step, it is shown the influence on the phase diagrams of considering different values for the \( T_\eta \) parameter in the effective potential (see Fig. 4). As expected it is observed a noticeable decrease of the chiral transition critical temperatures, but the smaller the temperature is the smaller is this decrease, converging to almost the same value when the critical temperature goes below \( T = 40 \text{ MeV} \). Also in Fig. 4 it can be seen a comparison between one of the nonlocal models (Set B as example) and the local one, where it is remarkable a difference of about 25 MeV along all the phase diagram lines for the same value of \( T_\mu \). But the main variation is in the location of the CEP, which in the case of the local model turns to be at a lower \( T \) and higher \( \mu \) than the nonlocal case. Comparing Figs. 5 and 6 for nonlocal and local models respectively, it can be observed that the influence of the increasing of the vector coupling strength is qualitatively similar in both cases, i.e. moving the phase transitions towards higher \( \mu \) values and lowering the CEP location. Nevertheless, in the case of the local model the CEP turns to disappear for higher values of \( \eta_V \), leaving only a crossover transition along all the phase diagrams.

A second step in our work consisted in the determination of the curvatures in the low \( \mu \) region as the slope of the straight lines obtained by plotting the pseudocritical temperatures of the crossover transitions as function of \((\mu/T)^2\). In Fig. 7 it is shown some examples of the lines obtained with Set C and several values of \( \eta_V \) while in Fig. 8 it can be observed how the curvatures vary respect to the vector coupling strength for all the parametrizations considered.

Once it has been determined the values of \( \eta_V \) that best reproduce the lattice QCD result \( \kappa = 0.059(2)(4) \) [43] for the curvature at low \( \mu \)-values, we have shown (Fig. 9) the nonlocal model phase diagrams for the obtained values of \( \eta_V \).

Finally, considering the more elaborated models (non local and with WFR, i.e. set B and set C), and the corresponding values of \( \eta_V \) adjusted to lattice QCD results, we suggest in Figure 10 the most likely zone where, according to our study, the CEP would be located.

Note that in this exploratory study the lattice QCD data for the quark propagator and for the curvature of the pseudocritical line are obtained with different lattice actions. A more consistent study should be based on the same discretization of the action, provide a continuum extrapolation and work with physical quark masses.

As a next step it is necessary to investigate the robustness of the results of the nonlocal PNJL models when modifying the choice of the Polyakov-loop potential taking into account recent developments [54–56] and, in particular, when going beyond the
mean field approximation. A scheme for going beyond the meanfield in nonlocal PNJL models by including hadronic correlations (bound states and their dissociation in the continuum of scattering states) has recently been developed [57] and shall be generalized for studies of the chiral and deconfinement phase transition in the QCD phase diagram. A key quantity for such studies will be the hadronic spectral function. First results using a generic ansatz [58] for joining the hadron resonance gas and PNJL approaches are promising [59, 60] and have recently been underpinned a microscopic justification by a treatment of pion dissociation within the (local) PNJL model [61]. This approach has recently been generalized by mimicking confining properties with an infrared momentum cutoff [62] in order to bind higher lying mesonic states such as the sigma meson—a feature shared with the nonlocal extensions of the (P)NJL model as, e.g., in [23, 47, 63, 64], to be exploited further in subsequent work.

ACKNOWLEDGMENTS

We would like to thank O. Kaczmarek, S. Nedelko, K. Redlich, C. Schmidt, N. Scoccola for useful comments and discussions. D.B. acknowledges hospitality and support during his visit at the University of Bielefeld and funding of his research provided by the Polish Narodowe Centrum Nauki within the “Maestro” programme under contract UMO-2011/02/A/ST2/00306 as well as by the Russian Fund for Basic Research under Grant No. 11-02-01538-a. G.C. is grateful for support by CONICET (Argentina) and by the Russian Fund for Basic Research under contract UMO-2011/02/A/ST2/00306.
